VISUAL SPHERE AND THURSTON'S BOUNDARY OF THE UNIVERSAL TEICHMÜLLER SPACE

HRANT HAKOBYAN AND DRAGOMIR ŠARIĆ

Abstract. Thurston's boundary to the universal Teichmüller space $T(\mathbb{D})$ is the space $PML_{bdd}(\mathbb{D})$ of projective bounded measured laminations of $\mathbb{D}$. A geodesic ray in $T(\mathbb{D})$ is of Teichmüller type if it shrinks vertical foliation of an integrable holomorphic quadratic differential. In a prior work we established that each Teichmüller geodesic ray limits to a multiple (by the reciprocal of the length of the leaves) of vertical foliation of the quadratic differential.

Certain non-integrable holomorphic quadratic differential induce geodesic rays and we consider their limit points in $PML_{bdd}(\mathbb{D})$. Somewhat surprisingly, the support of the limiting projective measured laminations might be a geodesic lamination whose leaves are not homotopic to leaves of either vertical or horizontal foliation of the non-integrable holomorphic quadratic differential.

1. Introduction

Let $\mathbb{D}$ be the unit disk model of the hyperbolic plane. The Teichmüller space $T(\mathbb{D})$ of the hyperbolic plane $\mathbb{D}$, called the *universal* Teichmüller space, consists of all quasisymmetric maps $h : S^1 \to S^1$ which fix 1, i and -1 (cf. [4]). The Teichmüller space of an arbitrary hyperbolic surface embeds in $T(\mathbb{D})$ as a complex Banach submanifold. Thurston's boundary to the universal Teichmüller space $T(\mathbb{D})$ is the space $PML_{bdd}(\mathbb{D})$ of projective bounded measured laminations of $\mathbb{D}$ (cf. [19], [21]). Teichmüller geodesic rays are obtained by shrinking vertical trajectories of integrable holomorphic quadratic differentials. A Teichmüller geodesic ray corresponding to an integrable holomorphic quadratic differential φ limits to a unique point in Thurston's boundary whose support geodesic lamination is homotopic to vertical foliation of φ and the transverse measure is given by integrating the reciprocal of the lengths of vertical leaves against $Re(\sqrt{\varphi dz^2})$ (cf. [8]). Certain non-integrable holomorphic quadratic differentials induce geodesic rays in $T(\mathbb{D})$ by shrinking their vertical trajectories in the same

fashion as for integrable differentials. We study the limits of these geodesic rays on Thurston's boundary to $T(\mathbb{D})$.

The space $G(\mathbb{D})$ of oriented geodesics of $\mathbb{D}$ is identified with $S^1 \times S^1 - diag$ since each geodesic is uniquely determined by the ordered pair of its ideal endpoints on S^1. A *geodesic current* is a positive Borel measure on $G(\mathbb{D})$. The universal Teichmüller space $T(\mathbb{D})$ embeds into the space of geodesic currents when equipped with the uniform weak* topology (cf. [21]). Thurston's boundary to $T(\mathbb{D})$ is the set of asymptotic rays to the image of $T(\mathbb{D})$ in the space of geodesic currents and it is identified with the space $PML_{bdd}(\mathbb{D})$ of projective bounded measured laminations of $\mathbb{D}$ (cf. [21]). This approach was first introduced by Bonahon [2] to give an alternative description of Thurston's boundary of the Teichmüller space $T(S)$ of a closed surface S of genus at least two.

In the case of closed surfaces, Masur [14] proved that Teichmüller geodesic rays obtained by shrinking vertical trajectories of holomorphic quadratic differentials with uniquely ergodic vertical foliations converge to the projective classes of their vertical foliations in Thurston's boundary. However, when vertical foliations of holomorphic quadratic differentials on closed surfaces are not uniquely ergodic then the limit sets of the corresponding Teichmüller geodesic rays consist of more than one point while their supports are homotopic to vertical foliation of the quadratic differential (cf. [13], [12]). On the other hand, the limits of Teichmüller geodesic rays in the universal Teichmüller space $T(\mathbb{D})$ corresponding to integrable holomorphic quadratic differentials always have a unique endpoint in Thurston's boundary of $T(\mathbb{D})$ (cf. [8]).

Let φ be an integrable holomorphic quadratic differential on $\mathbb{D}$. Each vertical trajectory of φ has two distinct endpoints on the boundary circle S^1 of the hyperbolic plane $\mathbb{D}$ (cf. [22]). Thus each vertical trajectory of φ is homotopic to a unique geodesic of $\mathbb{D}$ relative ideal endpoints on S^1. Let v_φ be the set of the geodesics in $\mathbb{D}$ homotopic to the vertical trajectories of φ. Given a box of geodesics $[a,b]\times[c,d] \subset S^1 \times S^1 - diag$, denote by $I_{[a,b]\times[c,d]}$ (at most countable) union of sub-arcs of horizontal trajectories that intersects exactly once each vertical trajectory of φ with one endpoint in $[a,b]$ and the other endpoint in $[c,d]$, and that does not intersect any other vertical trajectories of φ.

Define measured laminations ν_φ and μ_φ of $\mathbb{D}$ supported on v_φ by

$$\nu_\varphi([a,b]\times[c,d]) = \int_{I_{[a,b]\times[c,d]}} dx$$

and

$$\mu_\varphi([a,b]\times[c,d]) = \int_{I_{[a,b]\times[c,d]}} \frac{1}{l(x)}dx$$

where $x = \int_* \sqrt{\varphi}dz$ is the natural parameter of φ and $l(x)$ is the φ-length of the vertical trajectory through x (cf. [8]). Then (cf. [8])

$$\epsilon T_\epsilon \to \mu_\varphi$$

as $\epsilon \to 0^+$ in the weak* topology on geodesic currents, where T_ϵ is a quasiconformal map of $\mathbb{D}$ that shrinks the vertical trajectories of φ by a multiplicative constant ϵ. In other words, the Teichmüller geodesic ray T_ϵ converges to $[\mu_\varphi] \in PML_{bdd}(\mathbb{D})$.

The space of all geodesic rays in the Teichmüller metric starting at the basepoint $[id] \in T(\mathbb{D})$ leaving every bounded subset of $T(\mathbb{D})$ is called the *visual boundary* of the universal Teichmüller space $T(\mathbb{D})$. The *Teichmüller geodesic rays*-obtained by shrinking the vertical direction of an integrable holomorphic quadratic differential φ-form an open and dense subset of $T(\mathbb{D})$ (cf. [4]). However, there exist geodesic rays different from Teichmüller geodesic rays. A Beltrami coefficient ξ of a quasiconformal map $f : \mathbb{D} \to \mathbb{D}$ is said to be *extremal* if $\|\xi\|_\infty$ is minimal among all Beltrami coefficients of quasiconformal maps representing the same point in $T(\mathbb{D})$ (where $f, g : \mathbb{D} \to \mathbb{D}$ represent the same point of $T(\mathbb{D})$ if $f|_{S^1} = g|_{S^1}$ [4]). If an extremal Beltrami coefficient ξ is not of the Teichmüller type $k\frac{|\varphi|}{\varphi}$ for $0 < k < 1$ and φ integrable, then $t \mapsto t\xi$ for $t \in [0, \frac{1}{\|\xi\|_\infty})$ is a geodesic ray that is not a Teichmüller geodesic ray.

We consider the limits of two (non-Teichmüller) geodesic rays introduced by Strebel [4]. The first example is given by a horizontal strip $S = \{0 < Im(z) < 1\}$ with the Beltrami coefficient $\xi = k\frac{|\varphi|}{\varphi}$ with $\varphi(z) \equiv 1$. Since S does not have finite Euclidean area, the holomorphic quadratic differential φ is not integrable and the corresponding geodesic ray is not Teichmüller. Note that S is conformally identified with $\mathbb{D}$ and this identification is implicitly assumed. We denote by T_ϵ the shrinking of vertical trajectories by the factor ϵ and denote by $T_{1/\epsilon}$ the stretching of the vertical trajectories of φ by the factor $1/\epsilon$ as $\epsilon \to 0^+$. We prove (cf. Theorem 4.1 and Figure 1)

Theorem 1. *Let $S = \{0 < Im(z) < 1\}$ be a horizontal strip and let $\varphi(z) = 1$ for all $z \in S$. Denote by T_ϵ, $\epsilon > 0$, the geodesic ray in $T(\mathbb{D})$ obtained by shrinking the vertical leaves of φ by a factor ϵ and denote by $T_{\frac{1}{\epsilon}}$, $\epsilon > 0$, the geodesic ray in $T(\mathbb{D})$ obtained by stretching the vertical leaves by a factor $\frac{1}{\epsilon}$.*

Let ν_1 be the (hyperbolic) measured lamination on S whose support is homotopic to the vertical foliation of $\varphi(z) = 1$ on S and whose transverse measure is given by the euclidean length of the transverse horizontal set. Let ν_2 be the dirac measured lamination on S with support the hyperbolic geodesic homotopic to horizontal trajectories in S.

Then we have

$$T_\epsilon \to [\nu_1]$$

and

$$T_{1/\epsilon} \to [\nu_2]$$

as $\epsilon \to 0^+$ in Thuston's boundary $PML_{bdd}(\mathbb{D})$ of the universal Teichmüller space $T(\mathbb{D})$. The rate of convergence of T_ϵ is $1/\epsilon$ and the rate of convergence of $T_{1/\epsilon}$ is $1/\epsilon^*$, where $\epsilon^* \to 0^+$ as $\epsilon \to 0^+$.

Remark 1. Note that all vertical trajectories in S have finite φ-lengths which is the same as in the case of integrable holomorphic quadratic differentials. On the other hand, horizontal trajectories of φ have infinite lengths. Unlike for intergrable case, this makes the φ-metric unsuitable for making allowable metrics when computing moduli of various quadrilaterals and we find a new method for dealing with the difficulty.

Next we consider Strebel's chimney domain $C = \{z : Im(z) < 0\} \cup \{z : |Re(z)| < 1\}$. The holomorphic quadratic differential $\varphi(z)dz^2 = dz^2$ is not integrable on C while the corresponding Beltrami coefficient $k\frac{|\varphi|}{\varphi} = k$ is extremal. Denote by T_ϵ as $\epsilon \to 0^+$ the geodesic ray obtained by shrinking the vertical foliation of φ by the factor ϵ. We prove (cf. Theorem 4.3 and Figure 2)

Theorem 2. *Let ν be a measured lamination on C which is a sum of two Dirac measured laminations supported on geodesics γ_1 and γ_2 in C with endpoints $1, +\infty \in \partial C$ and endpoints $-1, +\infty \in \partial C$, respectively. Then*

$$T_\epsilon \to [\nu]$$

as $\epsilon \to 0^+$ in Thuston's closure $T(\mathbb{D}) \cup PML_{bdd}(\mathbb{D})$ of the universal Teichmüller space $T(\mathbb{D})$. The rate of convergence of T_ϵ is $1/\epsilon^*$, where $\epsilon^* \to 0^+$ as $\epsilon \to 0^+$.

Remark 2. All vertical leaves on C have infinite lengths. If vertical leaves are straightened into hyperbolic geodesics, then the geodesic lamination v_φ does not contain g_1 and g_2 even in its closure. Therefore it is impossible to detect g_1 and g_2 just by v_φ alone. In fact, the limits

g_1 and g_2 appear due to the fact that vertical trajectories accumulate to parts of the boundary of C.

2. Thurston's boundary via geodesic currents

We identify the hyperbolic plane with its upper half-plane model $\mathbb{D}$; the visual boundary $S^1 = \mathbb{R} \cup \{\infty\}$ to $\mathbb{D}$ is homeomorphic to the unit circle. An orientation preserving homeomorphism $h : S^1 \to S^1$ is said to be *quasisymmetric* if there exists $M \geq 1$ such that

$$\frac{1}{M} \leq \frac{|h(e^{x+t}) - h(e^x)|}{|h(e^x) - h(e^{x-t})|} \leq M$$

for all $x \in \mathbb{R}$ and $t > 0$. A homeomorphism is quasisymmetric if and only if it extends to a quasiconformal map of the unit disk.

Definition 2.1. The universal Teichmüller space $T(\mathbb{D})$ consists of all quasisymmetric maps $h : S^1 \to S^1$ that fix $1, i, -1 \in S^1$.

If $g : \mathbb{D} \to \mathbb{D}$ is a quasiconformal map, denote by $K(g)$ its quasiconformal constant. The Teichmüller metric on $T(\mathbb{D})$ is given by $d(h_1, h_2) = \inf_g K(g)$, where g runs over all quasiconformal extensions of the quasisymmetric map $h_1 \circ h_2^{-1}$. The Teichmüller topology is induced by the Teichmüller metric.

The space $G(\mathbb{D})$ of oriented geodesics on $\mathbb{D}$ is identified with $S^1 \times S^1 - diag$. A *geodesic current* is a Borel measure on $G(\mathbb{D})$. The *Liouville measure* $\mathcal{L}$ on the space of geodesic of $\mathbb{D}$ is given by

$$\mathcal{L}(A) = \int_A \frac{|dx||dy|}{|x - y|^2}$$

for any Borel set $A \subset S^1 \times S^1 - diag$. If $A = [a, b] \times [c, d]$ is a *box of geodesic* then

$$\mathcal{L}([a, b] \times [c, d]) = \log \frac{(a - c)(b - d)}{(a - d)(b - c)}.$$

The universal Teichmüller space $T(\mathbb{D})$ maps into the space of geodesic currents by taking the pull backs by quasisymmetric maps of the Liouville measure. A geodesic current α is *bounded* if

$$\sup_{[a,b]\times[c,d]} \alpha([a, b] \times [c, d]) < \infty$$

where the supremum is over all boxes of geodesics $[a, b] \times [c, d]$ with $\mathcal{L}([a, b] \times [c, d]) = \log 2$. The pull backs $h^*(\mathcal{L})$ for h quasisymmetric are bounded geodesic currents (cf. [19]).

The pull backs of the Liouville measure define a homeomorphism of $T(\mathbb{D})$ onto its image in the bounded geodesic currents, when the

space of geodesic currents is equipped with the uniform weak* topology ([21]). The asymptotic rays to the image of $T(\mathbb{D})$ are identified with the space of projective bounded measured laminations (cf. [21], [19]). Thus Thurston's boundary of $T(\mathbb{D})$ is the space $PML_{bdd}(\mathbb{D})$ of all projective bounded measured laminations on $\mathbb{D}$ (and an analogous statement holds for any hyperbolic Riemann surface). Bonahon [2] introduced this approach for closed surfaces in order to give an alternative definition of Thurston's boundary.

3. The asymptotics of the modulus

Let (a, b, c, d) be a quadruple of distinct points on S^1 given in the counterclockwise order. Denote by $\Gamma_{[a,b]\times[c,d]}$ the family of all differentiable curves whose interiors are in $\mathbb{D}$ that have one endpoint on the arc $[a, b] \subset S^1$ and the other endpoint on the arc $[c, d] \in S^1$. An *admissible metric* ρ for the family $\Gamma_{[a,b]\times[c,d]}$ is a non-negative measurable function on $\mathbb{D}$ such that the ρ-length of each $\gamma \in \Gamma_{[a,b]\times[c,d]}$ is at least one, namely

$$l_\rho(\gamma) = \int_\gamma \rho(z)|dz| \geq 1.$$

The *modulus* $\mathrm{mod}(\Gamma_{[a,b]\times[c,d]})$ of the family $\Gamma_{[a,b]\times[c,d]}$ is given by

$$\mathrm{mod}(\Gamma_{[a,b]\times[c,d]}) = \inf_\rho \int_{\mathbb{D}} \rho(z)^2 dxdy$$

where the infimum is over all admissible metrics ρ.

Lemma 3.1 below, summarizes some of the main properties of the modulus, which we will use repeatedly throughout the paper. We refer the reader to [5, 11, 23] for the proofs of these properties below and for further background on modulus.

If Γ_1 and Γ_2 are curve families in $\mathbb{C}$, we will say that Γ_1 *overflows* Γ_2 and will write $\Gamma_1 > \Gamma_2$ if every curve $\gamma_1 \in \Gamma_1$ contains some curve $\gamma_2 \in \Gamma_2$.

Lemma 3.1. *Let $\Gamma_1, \Gamma_2, \ldots$ be curve families in $\mathbb{C}$. Then*

1. Monotonicity: *If $\Gamma_1 \subset \Gamma_2$ then* $\mathrm{mod}(\Gamma_1) \leq \mathrm{mod}(\Gamma_2)$.
2. Subadditivity: $\mathrm{mod}(\bigcup_{i=1}^\infty \Gamma_i) \leq \sum_{i=1}^\infty \mathrm{mod}(\Gamma_i)$.
3. Overflowing: *If $\Gamma_1 < \Gamma_2$ then* $\mathrm{mod}\Gamma_1 \geq \mathrm{mod}\Gamma_2$.

We will mostly be interested in estimating moduli of families of curves in a domain $\Omega \subset \mathbb{C}$ connecting two subsets of the boundary of Ω. Thus, given $E, F \subset \partial\Omega$ we denote

$$(E, F; \Omega) = \{\gamma : [0, 1] \to \Omega : \gamma(0) \in E \text{ and } \gamma(1) \in F\} \tag{1}$$

the family of curves γ starting in E and terminating in F. With this notation we have

$$\Gamma_{[a,b]\times[c,d]} = ((a,b),(c,d);\mathbb{D}).$$

If the domain Ω is clear from the context, we will suppress it from the notation and just write $\Gamma_{E,F}$ instead of $(E,F;\Omega)$.

Heuristically modulus of $(E,F;\Omega)$ measures the amount of curves connecting E and F in the Ω. The more "short" curves they are the bigger the modulus is. This heuristic may be made precise using a notion of relative distance $\Delta(E,F)$, which we define next.

Given two continua E and F in $\mathbb{C}$ we denote

$$\Delta(E,F) := \frac{\operatorname{dist}(E,F)}{\min\{\operatorname{diam}E, \operatorname{diam}F\}}, \tag{2}$$

i.e. $\Delta(E,F)$ is the *relative distance* between E and F in $\mathbb{C}$.

Lemma 3.2 (cf. [8])**.** *For every pair of continua $E, F \subset \mathbb{C}$ we have*

$$\operatorname{mod}(E,F;\mathbb{C}) \leq \pi\left(1+\frac{1}{2\Delta(E,F)}\right)^2. \tag{3}$$

Corollary 3.3. *Let E_n and F_n, $n \in \mathbb{N}$, be a sequence of pairs of continua in $\mathbb{C}$. If the sequence $\Delta(E_n,F_n)$ is bounded away from 0 then* $\operatorname{mod}(E_n,F_n;\mathbb{C})$ *is bounded.*

Remark 3.4. The previous lemma is very weak for large $\Delta(E,F)$, since it is in fact easy to see that $\operatorname{mod}(E,F,\mathbb{C})$ tends to 0 as $\Delta(E,F)\to\infty$. But we will not need this estimate in the present paper and will refer the interested reader to Heinonen's book [9] for relations between the modulus and relative distance.

The following lemma is an easy consequence of the asymptotic properties of the moduli (cf. [11]).

Lemma 3.5 (cf. [7])**.** *Let (a,b,c,d) be a quadruple of points on S^1 in the counterclockwise order. Let $\Gamma_{[a,b]\times[c,d]}$ consist of all differentiable curves γ in $\mathbb{D}$ which connect $[a,b]\subset S^1$ with $[c,d]\subset S^1$. Then*

$$\operatorname{mod}(\Gamma_{[a,b]\times[c,d]}) - \frac{1}{\pi}\mathcal{L}([a,b]\times[c,d]) - \frac{2}{\pi}\log 4 \to 0$$

as $\operatorname{mod}(\Gamma_{[a,b]\times[c,d]})\to\infty$*, where $\mathcal{L}$ is the Liouville measure.*

Remark 3.6. Note that simultaneously $\operatorname{mod}(\Gamma_{[a,b]\times[c,d]})\to\infty$ and $\mathcal{L}([a,b]\times[c,d])\to\infty$. Therefore it is enough to consider the asymptotic behaviour of the modulus in order to find the asymptotic behaviour of the Liouville measure.

4. The visual sphere of $T(\mathbb{D})$

The visual sphere of the universal Teichmüller space $T(\mathbb{D})$, by definition, consists of all *unbounded* geodesic rays for the Teichmüller metric starting at the basepoint $id \in T(\mathbb{D})$. If a geodesic ray is a *Teichmüller ray* $t \mapsto t\frac{|\varphi|}{\varphi}$ for $t \in [0,1)$ and φ integrable holomorphic quadratic differential, then the limit on Thurston's boundary equals to the projective class of $\mu_\varphi \in ML_{bdd}(\mathbb{D})$ (cf. [8]). If η is an extremal Beltrami coefficient in its Teichmüller class, then $t \mapsto t\eta$ for $t \in [0, \frac{1}{\|\eta\|_\infty})$ defines a geodesic ray (cf. [4]) and it corresponds to a single point on the visual sphere. An interesting question is whether there exists a point on Thurston's boundary to which the geodesic ray defined by an extremal Beltrami coefficient (not given in the Teichmüller form $k\frac{|\varphi|}{\varphi}$) converges. We consider two examples of such geodesic rays both given by $t \mapsto t\frac{|\varphi|}{\varphi}$ for $t \in [0,1)$, where φ is a holomorphic quadratic differential that is not integrable on $\mathbb{D}$.

4.1. **The horizontal strip.** Consider a holomorphic quadratic differential $\varphi(z)dz^2 = dz^2$ on the horizontal strip $S = \{z : 0 < Im(z) < 1\}$. Strebel (cf. [22]) proved that the corresponding Beltrami coefficient $k\frac{|\varphi(z)|}{\varphi(z)} = k$ is extremal. Note that dz^2 is not integrable since the euclidean area of S is infinite. We consider two geodesic rays: the shrinking T_ϵ along the vertical foliation by the factor $\epsilon > 0$ as $\epsilon \to 0^+$ and the stretching $T_{1/\epsilon}$ along the vertical foliation by the factor $\epsilon > 0$ as $\epsilon \to 0^+$.

Theorem 4.1. *Let ν_1 be the (hyperbolic) measured lamination on S whose support is homotopic to the vertical foliation of dz^2 on S and whose transverse measure is given by the length in the natural parameter of the transverse horizontal set. Let ν_2 be the dirac measured lamination on S with support the hyperbolic geodesic homotopic to a horizontal trajectory in S. Then we have*

$$\epsilon(T_\epsilon)^*(\mathcal{L}) \to \nu_1$$

and

$$\epsilon^*(T_{1/\epsilon})^*(\mathcal{L}) \to \nu_2$$

where $\epsilon^* \to 0^+$ as $\epsilon \to 0^+$; $(T_\epsilon)^*(\mathcal{L})$ is the pull-back of the Liouville geodesic current by the boundary map of T_ϵ; similar for $(T_{1/\epsilon})^*(\mathcal{L})$. The convergence is in the weak topology.*

The first convergence follows directly from the considerations for integrable holomorphic quadratic differentials in [7] and [8]. It remains to prove the second convergence in the above Theorem. We note that

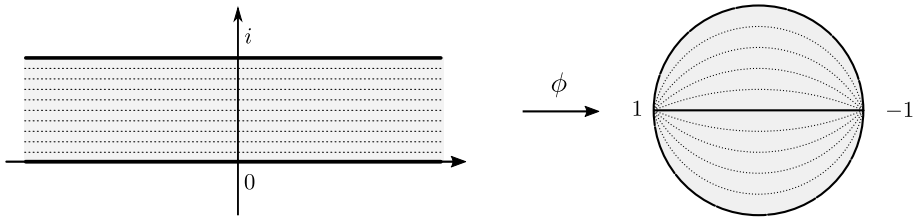

FIGURE 1. Horizontal strip S and its Riemann map. The dotted lines represent the horizontal trajectories of the standard quadratic differential dz^2 in S and their images in $\mathbb{D}$ under ϕ.

stretching the vertical direction by $1/\epsilon$ is equivalent to shrinking the horizontal direction by ϵ.

For a pair of intervals of prime ends $I, J \subset \partial S$ we denote by $\Gamma_{I,J}$ the family of curves connecting I and J in the strip S, i.e. $\Gamma_{I,J} = (I, J; S)$ according to the notation used in Section 3. Let $\Gamma^{\varepsilon}_{I,J} = H_{\varepsilon}(\Gamma_{I,J})$, where $H_{\varepsilon}(x, y) = (\varepsilon x, y)$. Since $H(S) = S$ we have for $\varepsilon > 0$

$$\Gamma^{\varepsilon}_{I,J} = (H_{\varepsilon}(I), H_{\varepsilon}(J); S). \tag{4}$$

We will denote by ϕ the Riemann mapping from S to the unit disc $\mathbb{D}$. By Caratheodory's theorem ϕ extends to ∂S and we will denote the extension by ϕ as well. Note that ϕ can be chosen to satisfy the following properties for $x \in \mathbb{R}$:

$$\phi(0) = -i, \tag{5}$$

$$\phi(i) = i, \tag{6}$$

$$\phi(x + iy) \to \pm 1, \text{ as } x \to \pm\infty, y \in (0, 1). \tag{7}$$

Let

$$\begin{aligned} I_0 &= (-\infty, 0) \cup (-\infty + i, i), \\ J_0 &= (1, \infty) \cup (1 + i, \infty + i). \end{aligned}$$

Recall that a sequence of Borel measures m_k on $S^1 \times S^1 - diag$ converges in the weak* topology to a Borel measure m if for every box $[a, b] \times [c, d]$ with $m(\partial([a, b] \times [c, d])) = 0$ we have $m_k([a, b] \times [c, d]) \to m([a, b] \times [c, d])$ as $k \to \infty$. Then Theorem 4.1 follows directly from the next lemma and the fact that $\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0} \to \infty$ as $\epsilon \to 0^+$ (cf. (12)) by setting $\varepsilon^* = 1/\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}$.

Lemma 4.2. *If $I, J \subset \partial S$ are disjoint intervals of prime ends s.t. $\mathrm{mod}\Gamma_{I,J} < \infty$ and the endpoints of $\phi(I)$ and $\phi(J)$ are disjoint from* 1

and -1 *then*

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}=\begin{cases}1, & \text{if } -1\in\phi(I) \text{ and } 1\in\phi(J),\\ 1, & \text{if } 1\in\phi(I) \text{ and } -1\in\phi(J),\\ 0, & \text{otherwise .}\end{cases} \tag{8}$$

Proof. First we show that if $-1\in\phi(I)$ and $1\in\phi(J)$ then $\mathrm{mod}\Gamma^{\varepsilon}_{I,J}\to\infty$ as $\varepsilon\to 0$. For this let $I'\subset\mathbb{R}$ and $I''\subset(\mathbb{R}+i)$ be the two complementary intervals of the set $I\cup J$ in ∂S. Then, since the curves connecting I and J are exactly those which separate I' from I'', it follows that

$$\mathrm{mod}\Gamma^{\varepsilon}_{I',I''}=(\mathrm{mod}\Gamma^{\varepsilon}_{I,J})^{-1},$$

and it is enough to show that $\mathrm{mod}\Gamma^{\varepsilon}_{I',I''}\to 0$ as $\varepsilon\to 0$. By monotonicity of modulus we have

$$\mathrm{mod}\Gamma^{\varepsilon}_{I',I''}=\mathrm{mod}\Gamma_{\varepsilon I',\varepsilon I''}\leq\mathrm{mod}\Gamma_{\varepsilon I',\mathbb{R}+i},$$

where $\varepsilon I'=\{\varepsilon x\in\mathbb{R}: x\in I'\}$ and $\varepsilon I''=\{\varepsilon x+i\in\mathbb{R}+i: x+i\in I''\}$. To show that the last quantity tends to zero let z_ε be the center of the interval $\varepsilon I'\subset\mathbb{R}$ and denote by $\Gamma_{\varepsilon I'}$ the family of curves connecting the boundary components of the annulus

$$\left\{z\in\mathbb{C}:\frac{\varepsilon|I'|}{2}<|z-z_\varepsilon|<1\right\}.$$

Since $\Gamma_{\varepsilon I',\mathbb{R}+i}$ overflows $\Gamma_{\varepsilon I'}$, we have

$$\mathrm{mod}\Gamma_{\varepsilon I',\mathbb{R}+i}\leq\mathrm{mod}\Gamma_{\varepsilon I'}\leq\frac{2\pi}{\log\frac{2}{\varepsilon|I|}}\to 0,\ \text{as } \varepsilon\to 0.$$

Therefore $\mathrm{mod}\Gamma^{\varepsilon}_{I,J}=(\mathrm{mod}\Gamma^{\varepsilon}_{I',I''})^{-1}\to\infty$ and in particular the denominator in (8) also tends to ∞.

Case 1: Suppose

$$-1\notin\phi(I)\cup\phi(J). \tag{9}$$

We want to show that in this case the limit in (8) is 0. Since the denominator of the quotient in (8) tends to ∞ it will suffice to demonstrate that $\mathrm{mod}\Gamma^{\varepsilon}_{I,J}$ stays bounded as $\varepsilon\to 0$. We consider the following subcases:

Case 1.1*:* Suppose, in addition to (9), we also have

$$1\notin\phi(I)\cup\phi(J). \tag{10}$$

In particular, we have $\max(\mathrm{diam}I,\mathrm{diam}J)<\infty$. Thus, I and J are two bounded length intervals belonging either to the same boundary component of ∂S or to different components.

If I and J belong to the same component of ∂S (assume this component is $\mathbb{R}$) then considering the maps $F_\varepsilon = (\varepsilon^{-1}id)\circ H_\varepsilon$ we see that F_ε restricted to $\mathbb{R}$ is the indentity, and in particular $H_\varepsilon(I) = I$ and $H_\varepsilon(J) = J$. Therefore, by conformal invariance of $\varepsilon^{-1}id$ we have,

$$\mathrm{mod}\Gamma^\varepsilon_{I,J} = \mathrm{mod}(H_\varepsilon(I), H_\varepsilon(J); H_\varepsilon(S)) = \mathrm{mod}(I, J; F_\varepsilon(S)) \leq \mathrm{mod}(I, J; \mathbb{C}),$$

where, as before, $(I, J; \Omega)$ denotes the collection of curves connecting I and J in the domain Ω. Since I and J are bounded fixed intervals a certain distance apart, we have that $\Delta(I, J) > 0$ and inequality (3) implies that $\mathrm{mod}(I, J; \mathbb{C})$ is finite and therefore $\mathrm{mod}\Gamma^\varepsilon_{I,J}$ is bounded for all $\varepsilon > 0$ and (8) holds in this case.

Case 1.2: Suppose

$$1 \in \phi(I) \cup \phi(J). \tag{11}$$

Without loss of generality we may assume that $1 \in \phi(J)$ and by (9) then I belongs to one of the components of ∂S, say $\mathbb{R}$, and $\mathrm{diam}I < \infty$. By our normalization of ϕ, this means that

$$\begin{aligned} I &= (a, b), \\ J &= (c, \infty) \cup (d + i, \infty + i). \end{aligned}$$

By subadditivity and monotonicity of modulus we have

$$\begin{aligned} \mathrm{mod}\Gamma^\varepsilon_{I,J} &\leq \mathrm{mod}\Gamma^\varepsilon_{I,(c,\infty)} + \mathrm{mod}\Gamma^\varepsilon_{I,(d+i,\infty+i)} \\ &\leq \mathrm{mod}\Gamma^\varepsilon_{I,(c,\infty)} + \mathrm{mod}\Gamma^\varepsilon_{I,\mathbb{R}+i}. \end{aligned}$$

Just like in the beginning of the proof, $\mathrm{mod}\Gamma^\varepsilon_{I,\mathbb{R}+i} \leq c(\log \frac{2}{\varepsilon \mathrm{diam}I})^{-1} \to 0$. Moreover, considering the maps $(\varepsilon^{-1}id)\circ H_\varepsilon$ again, we see that

$$\mathrm{mod}\Gamma^\varepsilon_{I,(c,\infty)} \leq \mathrm{mod}(H_\varepsilon(I), H_\varepsilon((c, \infty)); H_\varepsilon(S)) \leq \mathrm{mod}(I, (c, \infty); \mathbb{C}).$$

Since $\Delta(I, (c, \infty)) > 0$, we have $\mathrm{mod}(I, (c, \infty); \mathbb{C}) < \infty$ and $\mathrm{mod}\Gamma^\varepsilon_{I,(c,\infty)}$ and $\mathrm{mod}\Gamma^\varepsilon_{I,J}$ are bounded as $\varepsilon \to 0$ in this case as well.

Case 2: $\{-1, 1\} \subseteq \phi(I) \cup \phi(J)$. Assume, without loss of generality, that

$$-1 \in \phi(I) \text{ and } 1 \in \phi(J),$$

i.e. there are real numbers $a, b, c, d \in \mathbb{R}$ s.t.

$$I = (-\infty, a) \cup (-\infty + i, b + i) \text{ and } J = (c, \infty) \cup (d + i, \infty + i).$$

Note, that

$$-1 \in \phi(I \cap I_0) \text{ and } 1 \in \phi(J \cap J_0).$$

Therefore,

$$\lim_{\varepsilon \to 0} \mathrm{mod}\Gamma^\varepsilon_{I\cap I_0, J\cap J_0} = \infty. \tag{12}$$

By monotonicity and subadditivity of modulus we have

$$\begin{aligned} \mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0} \le \mathrm{mod}\Gamma^{\varepsilon}_{I,J} \le & \mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0} \\ & + \mathrm{mod}\Gamma^{\varepsilon}_{I\setminus I_0,J\cap J_0} + \mathrm{mod}\Gamma^{\varepsilon}_{I,J\setminus J_0}, \end{aligned} \tag{13}$$

$$\begin{aligned} \mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0} \le \mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0} \le & \mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0} \\ & + \mathrm{mod}\Gamma^{\varepsilon}_{I_0\setminus I,J_0\cap J} + \mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0\setminus J}. \end{aligned} \tag{14}$$

Since $-1 \in \phi(I \cap I_0)$, we may write $I \setminus I_0 = I_1 \cup I_2$ where I_1, I_2 are (possibly empty) finite length intervals. By subadditivity, we have

$$\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus I_0,J\cap J_0} \le \mathrm{mod}\Gamma^{\varepsilon}_{I_1,J_0\cap J} + \mathrm{mod}\Gamma^{\varepsilon}_{I_1,J_0\cap J}.$$

Now, by Case 1.1 ($\mathrm{diam} I_i < \infty$ and $1 \in \phi(J \cap J_0)$) we have that $\mathrm{mod}\Gamma^{\varepsilon}_{I_1,J_0\cap J}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I_1,J_0\cap J}$ are both bounded and therefore, so is $\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus I_0,J\cap J_0}$. Thus,

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus I_0,J\cap J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}} = 0$$

The same argument also shows that

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J\setminus J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}} = 0.$$

Therefore, dividing all the terms in (13) by $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}$ and taking $\varepsilon \to 0$, results in

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}} = 1.$$

Similarly, (14) implies

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}} = 1,$$

and combining the last two equalities we obtain

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} = \lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}} \left(\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap I_0,J\cap J_0}}\right)^{-1} = 1,$$

as required. □

4.2. **The Strebel's chimney domain.** Let

$$C = \{z : Im(z) < 0\} \cup \{z : |Re(z)| < 1\}$$

be the Strebel's chimney domain (cf. [4]). The holomorphic quadratic differential $\varphi(z)dz^2 = dz^2$ is not integrable on C. However, Strebel proved that the corresponding Beltrami coefficient $k\frac{|\varphi|}{\varphi}$ is extremal.

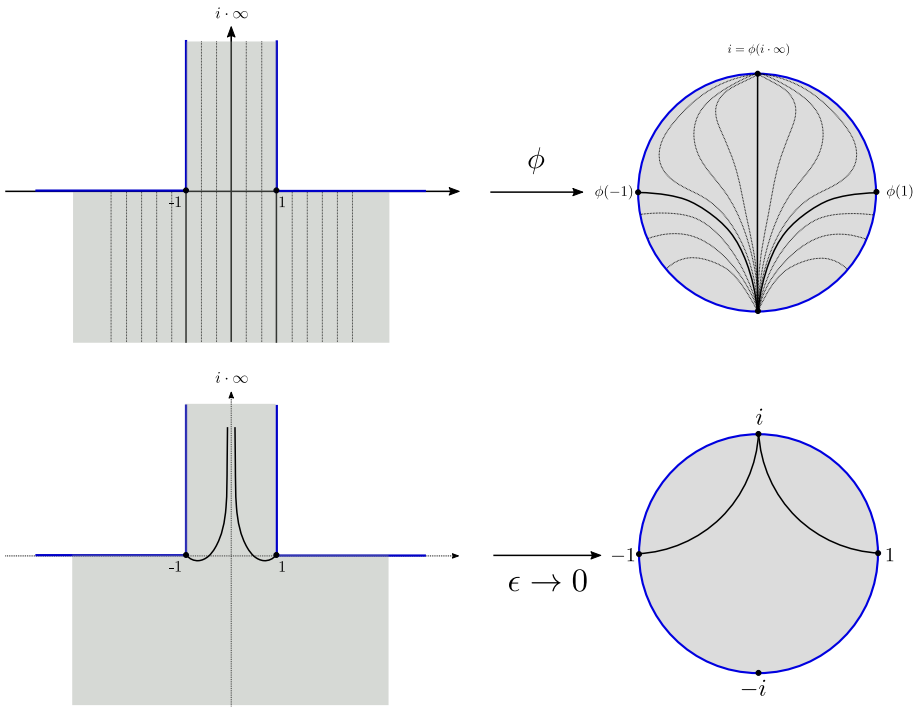

FIGURE 2. Strebel's chimney domain and its Riemann map. The dotted lines represent the vertical trajectories of the standard quadratic differential dz^2 in C and their images in $\mathbb{D}$ under ϕ.

We denote by ϕ the Riemann mapping from C to the unit disc $\mathbb{D}$. By Caratheodory's theorem ϕ extends to the ∂C and we will denote the extension by ϕ as well. Note that ϕ can be chosen to satisfy the following properties for $z \in C$:

$$\begin{aligned} \phi(\pm 1) &= \pm 1, \\ \phi(z) &\to +i, \text{ if } |z| \to \infty \text{ and } Im(z) > 0, \\ \phi(z) &\to -i, \text{ if } |z| \to \infty \text{ and } Im(z) < 0. \end{aligned}$$

Theorem 4.3. *Let ν be a measured lamination on C which is a sum of two Dirac measured laminations supported on geodesics γ_1 and γ_2 in C, where $\phi(\gamma_1), \phi(\gamma_2)$ are the hyperbolic geodesics in $\mathbb{D}$ connecting i to -1 and 1, respectively. Then*

$$\epsilon^*(T_\epsilon)^*(\mathcal{L}) \to \nu$$

where $\epsilon^* \to 0$ as $\epsilon \to 0^+$ and T_ϵ shrinks the vertical trajectories by the factor ϵ. As before, $(T_\epsilon)^*(\mathcal{L})$ is the pull back of the Liouville current $\mathcal{L}$ and the convergence is in the weak topology.*

To prove this theorem we reformulate it in terms of the limiting values of moduli of families of curves in C. Just like in the case of the strip, for a pair of intervals of prime ends $I, J \subset \partial C$ we denote by $\Gamma_{I,J}$ the family of curves connecting I and J in the domain C and let $\Gamma^\varepsilon_{I,J} = T_\varepsilon(\Gamma_{I,J})$, where $T_\varepsilon(x,y) = (x, \varepsilon y)$. Let us denote

$$I_0 = (1+i, 1+i\cdot\infty) = \{(1, iy) : 1 < y < \infty\},$$
$$J_0 = (1, 2).$$

Then we define $\epsilon^* = 1/\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0}$ and we need to prove that $\epsilon^* \to 0$ as $\epsilon \to 0$.

Theorem 4.4. *If $I, J \subset \partial C$ are disjoint intervals of prime ends s.t. $\mathrm{mod}\Gamma_{I,J} < \infty$ then*

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^\varepsilon_{I,J}}{\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0}} = \begin{cases} 0, & \text{if } i \notin \phi(I), \\ \#(\{-1,1\} \cap \phi(J)) & \text{if } i \in \phi(I). \end{cases} \tag{15}$$

Proof. First note that

$$\lim_{\varepsilon\to 0} \mathrm{mod}\Gamma^\varepsilon_{I_0,J_0} = \infty. \tag{16}$$

Indeed, letting $I' = [1, 1+i)$ and $J' = \partial C \setminus (I_0 \cup J_0 \cup I')$ we obtain $\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0} = (\mathrm{mod}\Gamma^\varepsilon_{I',J'})^{-1}$. Since $\Gamma^\varepsilon_{I',J'}$ overflows the family of curves connecting the boundary components of the annulus $A(1; \mathrm{diam}(T_\varepsilon(I')), 1)$ centered at $z = 1$ with radii $\mathrm{diam}(T_\varepsilon(I')) = \varepsilon$ and 1, we have

$$\mathrm{mod}\Gamma^\varepsilon_{I',J'} \le \frac{2\pi}{\log(\frac{1}{\varepsilon})} \to 0, \text{ as } \varepsilon \to 0,$$

and therefore $\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0} \to \infty$ as $\varepsilon \to 0$.

Now, let C_+, C_- denote the connected components of ∂C in the right and left half-planes, respectively. Furthermore, for an interval of prime ends $I \subset \partial C$ we let $I_\pm = I \cap C_\pm$. Therefore

$$\mathrm{mod}\Gamma^\varepsilon_{I,J} \le \mathrm{mod}\Gamma^\varepsilon_{I_+,J_+} + \mathrm{mod}\Gamma^\varepsilon_{I_-,J_-} + \mathrm{mod}\Gamma^\varepsilon_{I_+,J_-} + \mathrm{mod}\Gamma^\varepsilon_{I_-,J_+}. \tag{17}$$

Below we will prove the following lemma.

Lemma 4.5. *If $\mathrm{mod}\Gamma_{I,J} < \infty$ then $\mathrm{mod}\Gamma^\varepsilon_{I_-,J_+}$ and $\mathrm{mod}\Gamma^\varepsilon_{I_+,J_-}$ are bounded in ε.*

Therefore, Lemma 4.5 and (16) imply

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^\varepsilon_{I,J}}{\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0}} \le \lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^\varepsilon_{I_+,J_+}}{\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0}} + \lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^\varepsilon_{I_-,J_-}}{\mathrm{mod}\Gamma^\varepsilon_{I_0,J_0}}, \tag{18}$$

and we need estimates on $\mathrm{mod}\Gamma^\varepsilon_{I_+,J_+}$ and $\mathrm{mod}\Gamma^\varepsilon_{I_-,J_-}$. This is done in the next lemma.

Lemma 4.6. *If* $\mathrm{mod}\Gamma_{I,J} < \infty$ *then*

(a) *If* $i \notin \phi(I) \cup \phi(J)$ *then* $\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_-}$ *and* $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ *are bounded in* ε.
(b) *If* $i \in \phi(I)$ *and* $1 \notin \bar{J}_+$ *(resp.* $-1 \notin \bar{J}_-$*) then* $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ *(resp.* $\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_-}$*) is bounded in* ε.
(c) *If* $i \in \phi(I)$ *and* $1 \in J_+$ *(resp.* $-1 \in J_-$*) then*

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} = 1 \qquad \left(\textit{resp.} \ \lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_-}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} = 1. \right) \tag{19}$$

Let us prove the theorem assuming Lemma 4.6.

– If $i \notin \phi(I)$ then (18) and Lemma 4.6.(a) imply that limit in (15) is 0.

– If $i \in \phi(I)$ and $\#(\{-1,1\} \cap \phi(J)) = 0$ then by (18) and Lemma 4.6.(b) the limit in (15) is 0.

– If $i \in \phi(I)$ and $\#(\{-1,1\} \cap \phi(J)) = 1$, we may assume without loss of generality, that $1 \in \phi(J)$ but $-1 \notin \phi(J)$. Then, by (18) and Lemma 4.6.(b),(c) we have

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} \le 1 + 0.$$

Since also $\mathrm{mod}\Gamma^{\varepsilon}_{I,J} \ge \mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ we obtain that the limit in (15) is 1.

– If $\#(\{-1,1\} \cap \phi(J)) = 2$ then we have that in this case

$$i \in \phi(I) \text{ and } \{-1,1\} \subset \phi(J). \tag{20}$$

By (18) and Lemma 4.6.(c) we have

$$\lim_{\varepsilon\to 0} \frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} \le 1 + 1 = 2.$$

The rest of the proof is devoted to proving the opposite inequality. Note that in the previous case this easily followed from the monotonicity of the modulus. To estimate $\mathrm{mod}\Gamma^{\varepsilon}_{I,J}$ from below, we will compare it to $\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}$, where

$$\begin{aligned} \tilde{I} &:= (-1+i, -1+i\infty) \cup (1+i, 1+i\infty) \\ \tilde{J} &:= (-2,-1) \cup (1,2). \end{aligned}$$

We will show that if I and J satisfy conditions (20), then the following equalities hold:

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}}=1, \tag{21}$$

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}=2. \tag{22}$$

This will be sufficient for the proof of the theorem in this case, since multiplying (21) and (22) clearly yields equality (15) in this case.

Proof of equality (21). By monotonicity and subadditivity of the modulus, we have

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}\le \mathrm{mod}\Gamma^{\varepsilon}_{I,J}&\le \mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}+\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\setminus\tilde{J}}\\&\quad+\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus\tilde{I},J\cap\tilde{J}}+\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus\tilde{I},J\setminus\tilde{J}}.\end{aligned} \tag{23}$$

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}\le \mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}&\le \mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}+\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},\tilde{J}\setminus J}\\&\quad+\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus\tilde{I},J\cap\tilde{J}}+\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I}\setminus I,\tilde{J}\setminus J}.\end{aligned} \tag{24}$$

It is enough to show that all the terms on the right hand sides of (23) and (24) are bounded, except $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}$. Indeed, if this is the case then, since $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}\to\infty$, we will have

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{I,J}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}}=1,\quad\text{and}\quad\lim_{\varepsilon\to 0}\left(\frac{\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}}{\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\cap\tilde{J}}}\right)^{-1}=1.$$

Thus, multiplying the last two equations gives (21).

Now we show the boundedness of the mentioned moduli appearing in (23). The case of (24) is done in exactly the same way.

Since $i\in\phi(I)\cap\phi(\tilde{I})$ we have that $I\setminus\tilde{I}$ is a union of two (possibly empty) bounded segments. Therefore, subadditivity and part (a) of Lemma 4.6 implies that $\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus\tilde{I},J\cap\tilde{J}}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I\setminus\tilde{I},J\setminus\tilde{J}}$ are both bounded.

To estimate $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\setminus\tilde{J}}$ note, that since $\{-1,1\}\subset\phi(J)$ it follows that $-i\in\phi(J)$ and therefore

$$J\setminus\tilde{J}=(-\infty,-2]\cup J_1\cup J_2\cup[2,\infty),$$

where J_1 and J_2 are compact intervals in the vertical lines $\{Re(z)=\pm 1\}$, respectively. Therefore,

$$\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\setminus\tilde{J}}\le\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},[2,\infty)}+\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},(-\infty,-2]}+\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J_1\cup J_2}.$$

Now, $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},[2,\infty)}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},(-\infty,-2]}$ are bounded by Lemma 4.5 and part (b) of Lemma 4.6. Moreover, $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J_1}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J_2}$ are also both bounded, since the relative distance between, say, $T_\varepsilon(I\cap\tilde{I})$ and $T_\varepsilon(J_1)$ remains bounded away from 0 as $\varepsilon\to 0$. It follows that $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J_1\cup J_2}$ is bounded and therefore $\mathrm{mod}\Gamma^{\varepsilon}_{I\cap\tilde{I},J\setminus\tilde{J}}$ is bounded as well. □

Proof of equality (22). We first compare $\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}$. For this let

$$\Gamma^{\varepsilon,+}_{I_0,J_0} := \{\gamma\in\Gamma^{\varepsilon}_{I_0,J_0} : \gamma\subset\{Re(z)>0\}\},$$
$$\Gamma^{\varepsilon,0}_{I_0,J_0} := \{\gamma\in\Gamma^{\varepsilon}_{I_0,J_0} : \gamma\cap\{Re(z)=0\}\neq\emptyset\}.$$

Note that, since C and $\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}$ are both symmetric with respect to the imaginary axis, the symmetry rule for modulus (see [5], page 137) implies that

$$\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}} = 2\,\mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0}. \tag{25}$$

Moreover, by monotonicity and subadditivity of modulus we have

$$\mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0,} \le \mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0} \le \mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0} + \mathrm{mod}\Gamma^{\varepsilon,0}_{I_0,J_0}. \tag{26}$$

Since $T_\varepsilon(I_0)\subset[1,1+i\infty)$ we have that

$$\mathrm{mod}\Gamma^{\varepsilon,0}_{I_0,J_0} \le \mathrm{mod}\Gamma^{0}_{[1,1+i\infty),[1,2]}, \tag{27}$$

where the latter is the family of curves connecting $[1,1+i\infty)$ to $[1,2]$ in C which also intersect the imaginary axis $\{x=0\}$.

It is easy to see that $\mathrm{mod}\Gamma^{0}_{[1,1+i\infty),[1,2]}<\infty$. Indeed, letting Γ_1 and Γ_2 be the subfamilies of curves in $\Gamma^{0}_{[1,1+i\infty),[1,2]}$ starting in $[1,1+i]$ and $[1+i,1+i\infty)$, respectively, we have

$$\mathrm{mod}\Gamma^{0}_{[1,1+i\infty),[1,2]} \le \mathrm{mod}\Gamma_1 + \mathrm{mod}\Gamma_2.$$

Now, note that $\mathrm{mod}\Gamma_1<\infty$, since Γ_1 overflows the family of curves connecting $[1,1+i]$ to $\{Re(z)=0\}$, which has finite modulus (relative distance between $[1,1+i]$ and $\{Re(z)=0\}$ is $1>0$). Moreover, $\mathrm{mod}\Gamma_2\le 1$, since Γ_2 overflows the family of curves connecting the horizontal sides in the unit square $[0,1]\times[0,1]$.

Thus, $\mathrm{mod}\Gamma^{0}_{[1,1+i\infty),[1,2]}<\infty$, and by (27) we also have that $\mathrm{mod}\Gamma^{\varepsilon,0}_{I_0,J_0}$ is bounded independently of ε.

Since $\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}\to\infty$ and $\mathrm{mod}\Gamma^{\varepsilon,0}_{I_0,J_0}$ is bounded, it follows from (26) that

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}} = 1. \tag{28}$$

Finally, combining (25) and (28) we conclude, that

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}=\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{\tilde{I},\tilde{J}}}{\mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0}}\cdot\frac{\mathrm{mod}\Gamma^{\varepsilon,+}_{I_0,J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}=2\cdot 1=2, \tag{29}$$

which proves (22). □

Thus, to complete the proof of the theorem we only need to prove Lemmas 4.5 and 4.6. □

Proof of Lemma 4.5. We will show the boundedness of $\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_+}$. The case of $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_-}$ is done the same way.

There are two cases to consider:

Case 1. Suppose $\min(\mathrm{diam}I_-,\mathrm{diam}J_+)<\infty$. For concreteness we may assume $\mathrm{diam}I_-<\infty$. This means that there is a real number $1<a<\infty$ such that for $\varepsilon>0$ small enough we have

$$T_\varepsilon(I_-)\subset(-a,-1]\cup[-1,-1+i).$$

Therefore, since

$$\Delta(T_\varepsilon(I_-),T_\varepsilon(J_+))\geq\frac{2}{\mathrm{diam}(T_\varepsilon(I_-))}\geq\frac{2}{\sqrt{1+a^2}},$$

by Lemma 3.2 we have

$$\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_+}=\mathrm{mod}\Gamma_{T_\varepsilon(I_-),T_\varepsilon(J_+)}\leq\mathrm{mod}(T_\varepsilon(I_-),T_\varepsilon(J_+),\mathbb{C})<\infty.$$

Case 2. Suppose $\mathrm{diam}I_-=\mathrm{diam}J_+=\infty$. Since $\mathrm{mod}\Gamma_{I_-,J_+}\leq\mathrm{mod}\Gamma_{I,J}<\infty$ we have that

$$\min\{\mathrm{diam}(I_-\cap(-\infty,-1]),\mathrm{diam}(J_+\cap[1,\infty))\}<\infty,$$
$$\min\{\mathrm{diam}(I_-\cap\{Re(z)=-1\}),\mathrm{diam}(J_+\cap\{Re(z)=1\})\}<\infty.$$

For concreteness we may assume then, that

$$\mathrm{diam}(I_-\cap(-\infty,-1])<\infty,\ \text{and}\ \mathrm{diam}(J_+\cap\{Re(z)=1\})\}<\infty.$$

Therefore there is a real number $1<a<\infty$ such that for $\varepsilon>0$ small enough we have

$$T_\varepsilon(I_-)\subset(-a,-1]\cup[-1,-1+i\infty)\ \text{and}\ T_\varepsilon(J_+)\subset[1,\infty]\cup[1,1+i).$$

Therefore,

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_+}&\leq\mathrm{mod}\Gamma_{[-1,-1+i\infty),[1,\infty)}\\&\quad+\mathrm{mod}\Gamma_{[-1,-1+i\infty),[1,1+i)}+\mathrm{mod}\Gamma_{(-a,-1],[1,\infty)}+\mathrm{mod}\Gamma_{(-a,-1],[1,1+i)},\end{aligned} \tag{30}$$

where the last three terms are bounded by Case 1 above. On the other hand,

$$\mathrm{mod}\Gamma_{[-1,-1+i\infty),[1,\infty)}\leq\mathrm{mod}\Gamma_{[-1,-1+i),[1,\infty)}+\mathrm{mod}\Gamma_{[-1+i,-1+i\infty),[1,\infty)}.$$

Since $\Delta([-1,-1+i),[1,\infty))=2$ we have that the first term above is bounded. Moreover,

$$\mathrm{mod}\Gamma_{[-1+i,-1+i\infty),[1,\infty)}<2,$$

since $\Gamma_{[-1,-1+i\infty),[1,\infty)}$ overflows the "vertical family" of the rectangle $[-1,1]\times[0,1]$. Therefore

$$\mathrm{mod}\Gamma_{[-1,-1+i\infty),[1,\infty)}<\infty,$$

and by inequality (30) we have that $\mathrm{mod}\Gamma^{\varepsilon}_{I_-,J_+}$ is bounded. □

Proof of Lemma 4.6. We will estimate only $\mathrm{mod}\Gamma_{I_+,J_+}$. The estimates for $\mathrm{mod}\Gamma_{I_-,J_-}$ are done in a very similar way.

Case (a) : We first assume that $1\notin I_+\cup J_+$. Then we have the following subcases:
$(a1)$ If I_+ and J_+ belong to the same component of $C_+\setminus\{1\}$ then

$$\Delta(T_\varepsilon(I_+),T_\varepsilon(J_+))=\Delta(I_+,J_+)>0.$$

Therefore $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}\le\mathrm{mod}(T_\varepsilon(I_+),T_\varepsilon(J_+),\mathbb{C})$, which is bounded by Lemma 3.2.
$(a2)$ If $I_+\Subset(1,1+i\cdot\infty)$ and $J_+\Subset(1,\infty)$ then $T_\varepsilon(J_+)=J_+$ while $T_\varepsilon(I_+)$ is eventually contained in an interval $(1,1+\delta i)$ for every $\delta>0$. Therefore $\mathrm{dist}(T_\varepsilon(I_+),T_\varepsilon(J_+))\to\mathrm{dist}(\{0\},J_+)>0$, and $\mathrm{diam}T_\varepsilon(I_+)\to 0$ as $\varepsilon\to 0$. Thus, $\Delta(T_\varepsilon(I_+),T_\varepsilon(J_+))\to\infty$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ is bounded by Lemma 3.2.

If $1\in I_+\cup J_+$ then there are two more cases (we are assuming that I_+ is located to the left of J_+ when looking from inside C):
$(a3)$ If $1\in I_+$ while $J_+\subset(1,\infty)$ then $\Delta(T_\varepsilon(I_+),T_\varepsilon(J_+))\to\Delta(I_+\cap\mathbb{R},J_+)>0$, as $\varepsilon\to 0$ and therefore $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ is bounded.
$(a4)$ If $1\in J_+$ then we may assume that there are reals $0<c<a<b<\infty$ and $d>0$ such that $I_+=(1+ia,1+ib)$ and $J_+=[1,1+ic)\cup[1,d)$. Then

$$\Delta(T_\varepsilon(I_+),T_\varepsilon(J_+))=\frac{\varepsilon(a-c)}{\varepsilon c}=\frac{a}{c}-1>0$$

and $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}$ is bounded. The same arguments show that $\mathrm{mod}\Gamma_{I_-,J_-}$ is also bounded in this case.

Case (b) : If $i\in\phi(I)$ and $1\notin J_+$ (we also assume $1\notin\partial J_+$) then either $J_+\subset C_+\setminus\mathbb{R}$ or $J_+\Subset(1,\infty)$. In the former case the proof follows the same lines as in Case $(a1)$ above. Therefore we assume

$$i\in\phi(I)\text{ and }J_+\Subset(1,\infty).$$

Since $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+} \le \mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap\mathbb{R},J_+} + \mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus\mathbb{R},J_+}$ and

$$\mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap\mathbb{R},J_+} = \mathrm{mod}\Gamma_{I_+\cap\mathbb{R},J_+} \le \mathrm{mod}\Gamma_{I,J} < \infty,$$

we only need to show that $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus\mathbb{R},J_+}$ is bounded. By subadditivity,

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus\mathbb{R},J_+} &\le \mathrm{mod}\Gamma^{\varepsilon}_{[1,1+i\infty),J_+} = \mathrm{mod}\Gamma_{[1,1+i\infty),J_+}\\ &\le \mathrm{mod}\Gamma_{[1+i,1+i\infty),J_+} + \mathrm{mod}\Gamma_{[1,1+i),J_+}.\end{aligned}$$

Since $\mathrm{mod}\Gamma_{[1+i,1+i\infty),J_+} \le 2$ (because $\Gamma_{[1+i,1+i\infty),J_+}$ overflows the "vertical family" in the rectangle $[-1,1]\times[0,1]$), and $\mathrm{mod}\Gamma_{[1,1+i),J_+} < \infty$ since $\Delta([1,1+i),J_+) > 0$ (note that $\mathrm{dist}([1,1+i),J_+) > 0$), it follows that $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus\mathbb{R},J_+}$ is bounded.

Case (c) : If $I_+ \Subset [1,1+i\infty)$ then just like in case $(a4)$ above (with $b=\infty$), we have that $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+\setminus\mathbb{R}}$ is bounded. Therefore we only need to estimate $\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+\cap\mathbb{R}}$ and thus, we may assume $J_+\subset\mathbb{R}$. In particular, without loss of generality we assume that that there are reals $0<c<a<\infty$ and $1<d<\infty$ such that

$$I_+ = (1+ia, 1+i\infty) \text{ and } J_+ = [1,d).$$

Therefore

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+} &\le \mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\cap J_0} + \mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\setminus J_0}\\ &\quad + \mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus I_0,J_+\cap J_0} + \mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus I_0,J_+\setminus J_0}.\end{aligned}$$

- Now, if $J_+\subset J_0$ then $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\setminus J_0} = 0$. However, if $J_+\supset J_0$, then for every $I'\subset[1,1+i\infty)$ we have

$$\liminf_{\varepsilon\to 0}\Delta(T_\varepsilon(I'),T_\varepsilon(J_+\setminus J_0)) \ge \frac{1}{\mathrm{diam}(J_+\setminus J_0)} > 0. \tag{31}$$

In particular $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\setminus J_0}$ and $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus I_0,J_+\cap J_0}$ are both bounded as $\varepsilon\to 0$.

- Note, also that $\mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus I_0,J_+\cap J_0} \le \mathrm{mod}\Gamma^{\varepsilon}_{I_+\setminus I_0,[1,\infty)}$, which is bounded, since

$$\Delta(T_\varepsilon(I_+\setminus I_0),T_\varepsilon([1,\infty))) = \Delta(I_+\setminus I_0,[1,\infty)) > 0.$$

Since, $\mathrm{mod}\Gamma^{\epsilon}_{I_+,J_+} \ge \mathrm{mod}\Gamma^{\epsilon}_{I_0,J_0} \to \infty$ it follows that

$$\lim_{\varepsilon\to 0}\frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_+,J_+}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\cap J_0}} = 1. \tag{32}$$

Similarly, using the inequality

$$\begin{aligned}\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0} &\le \mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\cap J_0} + \mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_0\setminus J_+}\\ &\quad + \mathrm{mod}\Gamma^{\varepsilon}_{I_0\setminus I_+,J_+\cap J_0} + \mathrm{mod}\Gamma^{\varepsilon}_{I_0\setminus I_+,J_0\setminus J_+},\end{aligned}$$

we obtain

$$\lim_{\varepsilon\to 0}\left(\frac{\mathrm{mod}\Gamma^{\varepsilon}_{I_0,J_0}}{\mathrm{mod}\Gamma^{\varepsilon}_{I_+\cap I_0,J_+\cap J_0}}\right)^{-1}=1. \tag{33}$$

Finally, combining the last two equalities we obtain (19). □
